1 Preface

This document is targeted at developers and describes the overall structure and design of the CML simulator, it is not a detailed description of each component. This kind of documentation is done in Javadoc and can be generated automatically from the code. It is assumed that common design patterns are known like ??.

2 Overall Structure

This section describes the overall source code structure of the CML interpreter. At the top level the code can be split up in two separate components:

Core component Implements the operational semantics that are defined in [?] and is located in the java package named *eu.compassresearch.core.interpreter*

IDE component Exposes the core component to the Eclipse framework as an integrated debugger. It is located in the *eu.compassresearch.ide.cml.interpreter_plugin* package.

Each of these components will be described in further detail in the following sections.

2.1 The Core Structure

The design philosophy of the top-level structure is to encapsulate all the classes and interfaces that makes up the implementation of the core functionality and only expose those that are needed to utilize the interpreter. This provides a clean separation between the implementation and interface and makes it clear for both the users, which not necessarily wants to know about the implementation details, and developers which parts they need to work with.

The following packages defines the top level structure of the core:

eu.compassresearch.core.interpreter.api This package and sub-packages contains all the public classes and interfaces that defines the API of the interpreter. This package includes the main interpreter interface **Cm-Interpreter** along with additional interfaces. The api sub-packages

- 60 groups the rest of the API classes and interfaces according to the re-
61 sponsibility they have.
- 62 **eu.compassresearch.core.interpreter.api.behaviour** This package con-
63 tains all the components that define any CML behavior. A CML be-
64 haviour is either an observable event like a channel synchronization or
65 a internal event like a change of state. The main interface is **CmlBe-**
66 **haviour**.
- 67 **eu.compassresearch.core.interpreter.api.events** This package contains
68 all the public components that enable users of the interpreter to listen
69 on event from both **CmlIntepreter** and **CmlBehaviour** instances.
- 70 **eu.compassresearch.core.interpreter.api.transitions** This package con-
71 tains all the possible types of transitions that a **CmlBehaviour** in-
72 stance can make. This will be explained in more detail in section 3.1.1.
- 73 **eu.compassresearch.core.interpreter.api.values** This package contains
74 all the values used in the CML interpreter. Values are used to represent
75 the the result of an expression or the current state of a variable.
- 76 **eu.compassresearch.core.interpreter.debug** TBD
- 77 **eu.compassresearch.core.interpreter.utility** The utility packages con-
78 tains components that generally reusable classes and interfaces.
- 79 **eu.compassresearch.core.interpreter.utility.events** This package con-
80 tains components helps to implement the Observer pattern.
- 81 **eu.compassresearch.core.interpreter.utility.messaging** This package con-
82 tains general components to pass message along a stream.
- 83 **eu.compassresearch.core.interpreter** This package contains all the in-
84 ternal classes and interfaces that defines the core functionality of the
85 interpreter. There is one important public class in the package, namely
86 the **VanillaInterpreteFactory** faactory class, that any user of the
87 interpreter must invoke to use the interpreter. This can creates **Cm-**
88 **lInterpreter** instances.
- 89 The **eu.compassresearch.core.interpreter** package are split into several
90 folders, each representing a different logical component. The following folders
91 are present
- 92 **behavior** This folder contains all the internal classes and interfaces that
93 implements the CmlBehaviors. The Cml behaviors will be described in

94 more detail in in section 3.1, but they are basically implemented by
 95 CML AST visitor classes.

96 **factories** This folder contains all the factories in the package, both the pub-
 97 lic **VanillaInterpreteFactory** that creates the interpreter and pack-
 98 age internal ones.

99 **utility**

100 ...

101 2.2 The IDE Structure

102 The IDE part is integrating the interpreter into Eclipse, enabling CML mod-
 103 els to be debugged/simulated/animated through the Eclipse interface. In
 104 Figure 1 a deployment diagram of the debugging structure is shown.

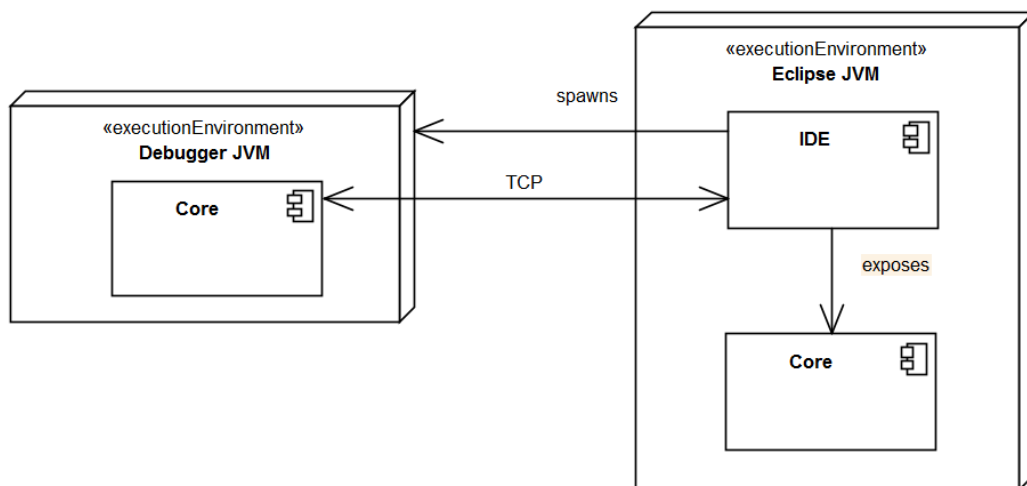

Figure 1: Deployment diagram of the debugger

105 An Eclipse debugging session involves two JVMs, the one that the Eclipse
 106 platform is executing in and one where only the Core executes in. All com-
 107 munication between them is done via a TCP connection.

108 Before explaining the steps involved in a debugging session, there are two
 109 important classes worth mentioning:

- 110 • **CmlInterpreterController**: This is responsible for controlling the
 111 CmlInterpreter execution in the debugger JVM. All communications
 112 to and from the interpreter handled in this class.

- **CmlDebugTarget**: This class is part of the Eclipse debugging model. It has the responsibility of representing a running interpreter on the Eclipse JVM side. All communications to and from the Eclipse debugger are handled in this class.

A debugging session has the following steps:

1. The user launches a debug session
2. On the Eclipse JVM a **CmlDebugTarget** instance is created, which listens for an incoming TCP connection.
3. A Debugger JVM is spawned and a **CmlInterpreterController** instance is created.
4. The **CmlInterpreterController** tries to connect to the created connection.
5. When the connection is established, the **CmlInterpreterController** instance will send a STARTING status message along with additional details
6. The **CmlDebugTarget** updates the GUI accordingly.
7. When the interpreter is running, status messages will be sent from **CmlInterpreterController** and commands and request messages are sent from **CmlDebugTarget**
8. This continues until **CmlInterpreterController** sends the STOPPED message

TBD...

3 Simulation/Animation

This section describes the static and dynamic structure of the components involved in simulating/animating a CML model.

3.1 Static Structure

The top level interface of the interpreter is depicted in figure 2, followed by a short description of each the depicted components.

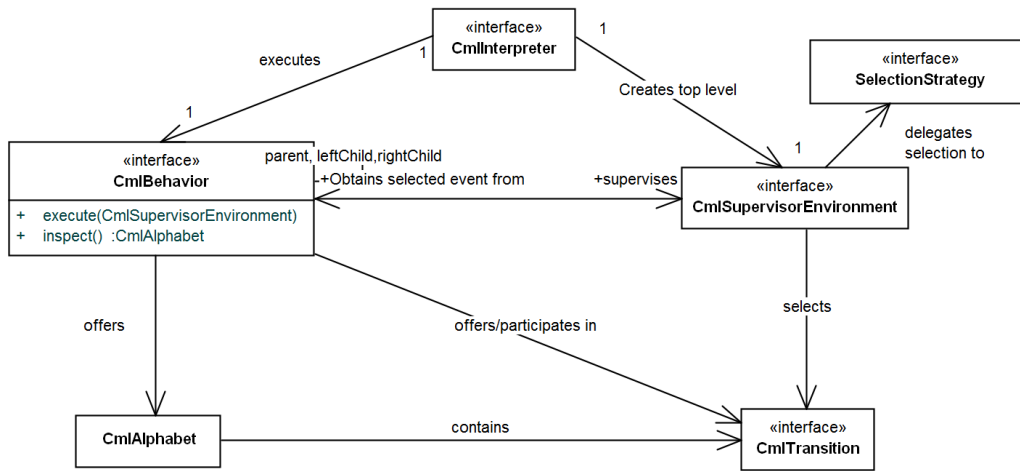

Figure 2: The high level classes and interfaces of the interpreter core component

141 **CmlInterpreter** The main interface exposed by the interpreter component.
 142 This interface has the overall responsibility of interpreting. It exposes
 143 methods to execute, listen on interpreter events and get the current
 144 state of the interpreter. It is implemented by the **VanillaCmlInter-**
 145 **preter** class.

146 **CmlBehaviour** Interface that represents a behaviour specified by either a
 147 CML process or action. It exposes two methods: *inspect* which cal-
 148 culates the immediate set of possible transitions that the current be-
 149 haviour allows and *execute* which takes one of the possible transi-
 150 tions determined by the supervisor. A specific behaviour can for instance
 151 be the prefix action “a -i P”, where the only possible transition is to
 152 interact in the a event. in any

153 **CmlSupervisorEnvironment** Interface with the responsibility of acting as
 154 the supervisor environment for CML processes and actions. A super-
 155 visor environment selects and exposes the next transition/event that
 156 should occur to its pupils (All the CmlBehaviors under its super-
 157 vision). It also resolves possible backtracking issues which may occur in
 158 the internal choice operator.

159 **SelectionStrategy** This interface has the responsibility of choosing an event
 160 from a given CmlAlphabet. This responsibility is delegated by the Cml-
 161 SupervisorEnvironment interface.

162 **CmlTransition** Interface that represents any kind of transition that a Cml-

163 Behavior can make. This structure will be described in more detail in
 164 section ??.

165 **CmlAlphabet** This class is a set of CmlTransitions. It exposes convenient
 166 methods for manipulating the set.

167 To gain a better understanding of figure 2 a few things needs mentioning.
 168 First of all any CML model (at least for now) has a top level Process. Be-
 169 cause of this, the interpreter need only to interact with the top level CmlBe-
 170 haviour instance. This explains the one-to-one correspondence between the
 171 CmlInterpreter and the CMLBehaviour. However, the behavior of top level
 172 CmlBehaviour is determined by the binary tree of CmlBehaviour instances
 173 that itself and it's child behaviours defines. So in effect, the CmlInterpreter
 174 controls every transition that any CmlBehaviour makes through the top level
 175 behaviour.

176 3.1.1 Transition Structure

177 As described in the previous section a CML model is represented by a binary
 178 tree of CmlBehaviour instances and each of these has a set of possible tran-
 179 sitions that they can make. A class diagram of all the classes and interfaces
 180 that makes up transitions are shown in figure 3, followed by a description of
 181 each of the elements.

182 A transition can be either observable or silent. An observable transition
 183 occurs either when time passes or a communication/synchronization takes
 184 place on a channel. All of these transitions are captured in the Observ-
 185 ableEvent interface. A silent transitions is captured by the SilentTransition
 186 interface and can either mark the occurrence of a hidden event or an internal
 187 transition.

188 **CmlTransition** Represents any possible transition.

189 **ObservableEvent** This represents any observable transition.

190 **ChannelEvent** This represents any event that occurs on a channel.

191 **CmlTock** This represents a Tock event marking the passage of a time unit.

192 **CommunicationEvent** This represents a communication event on a spe-
 193 cific channel and carries a value to be communicated.

194 **SynchronizationEvent** This represents a synchronization event on a spe-
 195 cific channel and carries no value.

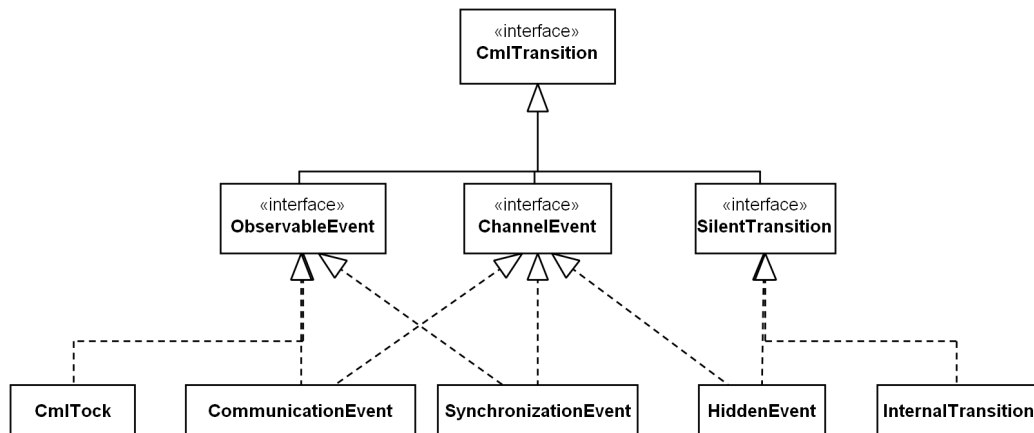

Figure 3: The classes and interfaces that defines transitions/events

196 **SilentTransition** This represents any non-observable transition.

197 **HiddenEvent** This represents an observable event that has been hidden by
198 the hiding operator.

199 **InternalTransition** This represents any transition that are internal to a
200 process, like assignemnt, the invocation of a method and etc.

201 3.1.2 Action/Process Structure

202 Actions and processes are both represented by the CmlBehaviour interface.
203 A class diagram of the important classes that implements this interface is
204 shown in figure 4

205 As shown the **ConcreteCmlBehavior** is the implementing class of the Cml-
206 Behavior interface. However, it delegates a large part of its responsibility
207 to other classes. The actual behavior of a ConcreteCmlBehavior instance
208 is decided by its current instance of the INode interface, so when a Con-
209 creteCmlBehavior instance is created a INode instance must be given. The
210 INode interface is implemented by all the CML AST nodes and can therefore
211 be any CML process or action. The actual implementation of the behavior
212 of any process/action is delegated to three different kinds of visitors all ex-
213 tending a generated abstract visitor that have the infrastructure to visit any
214 CML AST node.

215 The following three visitors are used:

216 **AbstractSetupVisitor** This has the responsibility of performing any re-

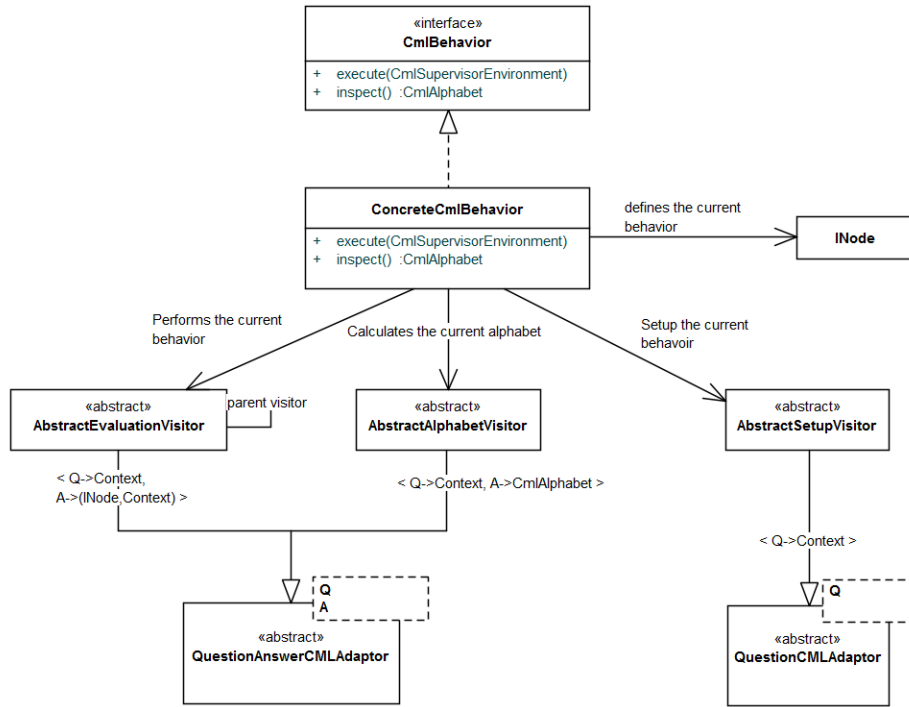

Figure 4: The implementing classes of the CmlBehavior interface

217 required setup for every behavior. This visitor is invoked whenever a
 218 new INode instance is loaded.

219 **AbstractEvaluationVisitor** This has the responsibility of performing the
 220 actual behavior and is invoked inside the **execute** method. This in-
 221 volves taking one of the possible transitions.

222 **AbstractAlphabetVisitor** This has the responsibility of calculating the
 223 alphabet of the current behavior and is invoked in the **inspect** method.

224 In figure 5 a more detailed look at the evaluation visitor structure is given.

225 As depicted the visitors are split into several visitors that handle different
 226 parts of the languages. The sole reason for doing this is to avoid having one
 227 large visitor that handles all the cases. At run-time the visitors are setup
 228 in a tree structure where the top most visitor is a **CmlEvaluationVisitor**
 229 instance which then delegates to either a **ActionEvaluationVisitor** and
 230 **ProcessEvaluationVisitor** etc.

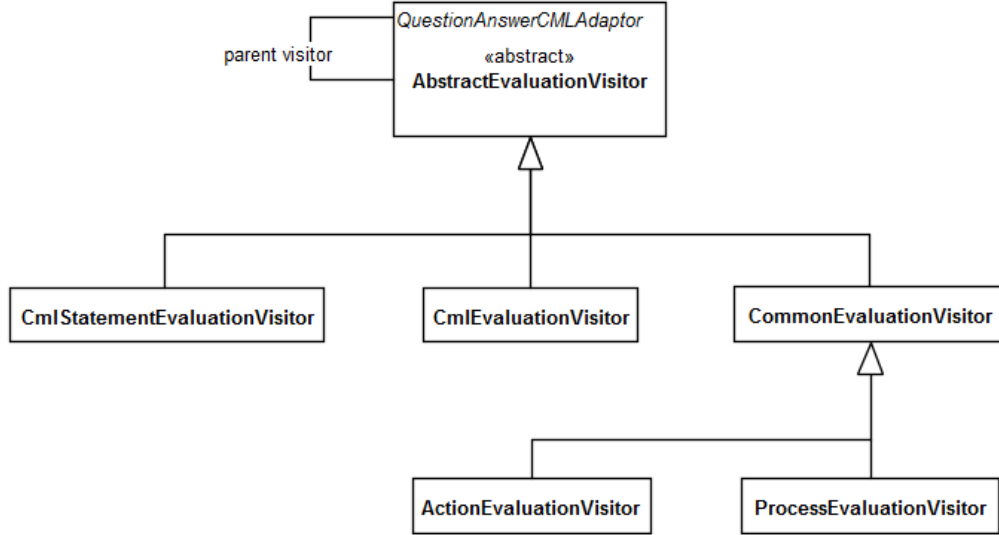

Figure 5: Visitor structure

231 3.2 Dynamic Structure

232 The previous section described the high-level static structure, this section
 233 will describe the high-level dynamic structure.

234 First of all, the entire CML interpreter runs in a single thread. This is mainly
 235 due to the inherent complexity of concurrent programming. You could argue
 236 that since a large part of COMPASS is about modelling complex concurrent
 237 systems, we also need a concurrent interpretation of the models. However,
 238 the semantics is perfectly implementable in a single thread which makes a
 239 multi-threaded interpreter optional. There are of course benefits to a multi-
 240 threaded interpreter such as performance, but for matters such as the testing
 241 and deterministic behaviour a single threaded interpreter is much easier to
 242 handle and comprehend.

243 To start a simulation/animation of a CML model, you first of all need an in-
 244 stance of the **CmlInterpreter** interface. This is created through the **Vanil-
 245 laInterpreterFactory** by invoking the **newInterpreter** method with a
 246 typechecked AST of the CML model. The currently returned implemen-
 247 tation is the **VanillaCmlInterpreter** class. Once a **CmlInterpreter** is
 248 instantiated the interpretation of the CML model is started by invoking the
 249 **execute** method given a **CmlSupervisorEnvironment**.

250 In figure 6 a high level sequence diagram of the **execute** method on the
 251 **VanillaCmlInterpreter** class is depicted.

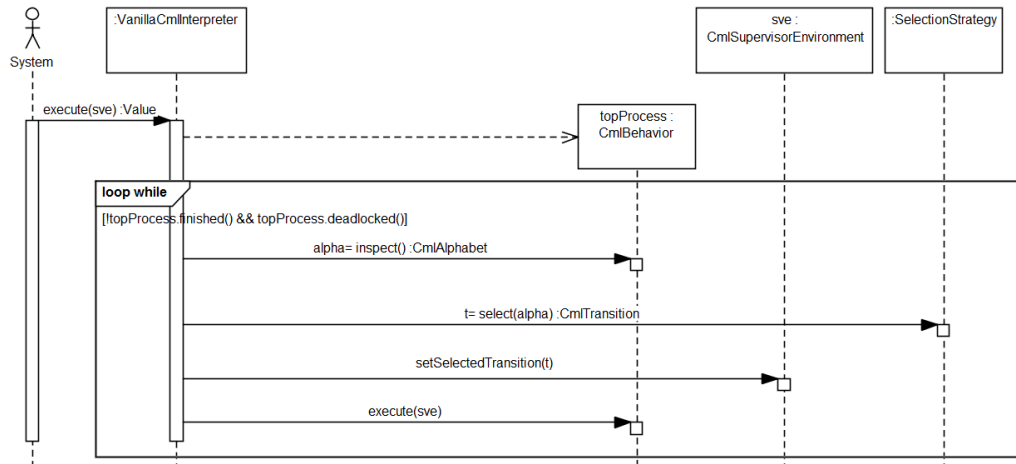

Figure 6: The top level dynamics

252 As seen in the figure the model is executed until the top level process is either
 253 successfully terminated or deadlocked. For each

254 3.2.1 CmlBehaviors

255 As explained in section ?? the CmlBehavior instances forms a binary tree at
 256 runtime.

257 4 The User Interface
